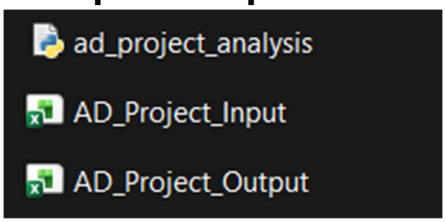
Complete Explanation of Input and Output Excel Files



Your project uses:
1. Input Excel File - "AD_Project_Input.xlsx"
and
2. Output Excel File – "AD_Project_Output.xlsx"
The input file gives raw experimental and process data to Python.
The output file gives final calculated results used for:

- thesis discussion
- Aspen Plus input
- model validation
- optimization work

PART 1 — INPUT EXCEL FILE
File Name:
AD_Project_Input.xlsx
This contains multiple sheets.

SHEET 1 — Daily_Methane

Purpose
This sheet stores:
daily cumulative methane production
from your BMP experiment.
This is the most important experimental data.

Example Table

Day	CH4_No_Biochar	CH4_5pct_Biochar	CH4_2pct	CH4_8pct	CH4_10pct
1	12	18	14	16	13
2	25	36	28	31	27
3	42	58	47	52	44
…	…	…	…	…	…
10	320	429	362	397	366

Meaning of Each Column
Day
Digestion day
Example:
Day 1 to Day 30

CH4_No_Biochar
Methane production without biochar
This is:
control experiment
Used as baseline.

CH4_5pct_Biochar
Methane production with fixed biochar dose
Example:

5%
Usually the best-performing case.

CH4_2pct, 8pct, 10pct
Methane production at different biochar dosages
Used for:
optimum dose selection

Why This Sheet Is Needed
Used for:

- methane yield calculation
- optimum biochar dose
- alpha calculation
- Gompertz fitting
- Aspen validation

Most important sheet.

SHEET 2 — Ultimate_Analysis

Purpose
This sheet stores:
elemental composition
of all non-conventional (NC) components.
Used for:

- Buswell equation
- Aspen NC component definition

Example Table

Material	C_wt%	H_wt%	O_wt%	N_wt%	Ash_wt%
FoodWaste	48.0	6.4	37.5	2.1	6.0
SB_Biochar_500	72.0	2.5	12.0	0.8	12.7
Digest	32.0	4.1	28.0	2.5	33.4

Meaning of Each Column
Material
Name of NC component:

- food waste
- sugarcane bagasse biochar
- digest

C, H, O, N
Ultimate analysis values
These are used in:
Buswell equation
for methane prediction.

Ash
Non-biodegradable solid content
Used for:
Aspen NC definition

Why This Sheet Is Needed
Used for:

- theoretical methane potential
- substrate validation

- RYIELD logic
- Aspen component setup

Very important.

SHEET 3 — Process_Inputs

Purpose
Stores:
model constants and assumptions
Used in Python and Aspen.

Example Table

Parameter	Value	Unit
VS_added	1.0	gVS
Optimum_Biochar_Dose	0.05	fraction
Base_k	0.25	day^{-1}

Meaning of Each Row

VS_added
Volatile solids added during BMP
Used in:
methane yield calculation

Optimum_Biochar_Dose
Best biochar amount
Example:
5% = 0.05
Used in:
alpha calculation
and
Aspen simulation

Base_k
Initial kinetic constant
Used for:
RCSTR reactor
before biochar enhancement.

Why This Sheet Is Needed
Used for:

- alpha calculation
- effective k calculation
- RCSTR setup

Very important.

PART 2 — OUTPUT EXCEL FILE
File Name:
AD_Project_Output.xlsx
This is generated automatically by Python.
This contains final calculated results.

SHEET 1 — Methane_Yield

Purpose
Shows methane yield comparison for all cases.

Example Table

Case	Methane_Yield
No Biochar	320
2% Biochar	362
5% Biochar	429
8% Biochar	397
10% Biochar	366

Why Important
This proves:
biochar improves methane production
and identifies:
optimum biochar dose

SHEET 2 — Alpha_Calc

Purpose
Shows:
biochar enhancement factor

Example Table

Parameter	Value
Y_without	320
Y_with	429
Biochar_Dose	0.05
Alpha	6.81

Why Important
Because:
biochar is unreacted
its effect must be represented mathematically.
This α is the heart of your thesis.

SHEET 3 — Kinetic_k

Purpose
Shows:
RCSTR effective kinetic constant

Example Table

Parameter	Value
Base_k	0.25
Effective_k	0.335

Why Important
This is the actual value used in:
Aspen RCSTR Power Law kinetics
This connects Python to Aspen.
Very important.

SHEET 4 — RYIELD_Table

Purpose
Defines decomposition in Aspen RYIELD.

Example Table

Product	Fraction
Acetate	0.44
H2	0.07
CO2	0.19
H2O	0.15
Digest	0.15

Why Important
This tells Aspen:
FOODWASTE
→ intermediates
and NOT directly methane.
This makes model scientifically correct.

Explanation and Algorithm of the Python Code for Biochar-Enhanced Anaerobic Digestion Modelling

1. Overview and Scientific Context

The presented Python script forms the computational bridge between **experimental laboratory data** and **process simulation in Aspen Plus** for an anaerobic digestion (AD) system amended with biochar. The core scientific premise – validated by the code – is that biochar acts as an **unreacted kinetic enhancer** rather than a stoichiometric reactant. Its sole effect is to increase the apparent first-order rate constant of acetoclastic methanogenesis.

The script processes three input sheets from AD_Project_Input.xlsx:

- Daily_Methane – cumulative methane production over digestion time (control and various biochar doses).
- Process_Inputs – model constants: volatile solids added (VS_added), optimum biochar dose (optional, overridden by automatic detection), and base kinetic constant (Base_k).
- Ultimate_Analysis – elemental composition (C, H, O, N, Ash) of food waste, biochar, and digestate.

It produces four output sheets in AD_Project_Output.xlsx:

1. Methane_Yield – normalised methane yields (mL CH_4/g VS) for all cases.
2. Alpha_Calc – the enhancement factor α and the data used to compute it.
3. Kinetic_k – the effective kinetic constant k_{eff} for the RCSTR in Aspen Plus.
4. RYIELD_Table – decomposition fractions of food waste into intermediates (acetate, H_2, CO_2, H_2O, digest) – derived dynamically from ultimate analysis.
5. Buswell_Validation – theoretical methane potential (Buswell equation) compared with the experimental optimum for validation.

The algorithm is designed to be **data-driven**, **reproducible**, and **aligned with the biochemical stages of AD** (hydrolysis → acidogenesis → acetogenesis → methanogenesis). Its key innovation is the automatic determination of the optimum biochar dose and the calculation of RYIELD fractions that are consistent with the feedstock's elemental composition.

2. Mathematical Foundation

2.1. Normalisation of Methane Yields

Raw cumulative methane values (mL) are normalised by the volatile solids added (g VS) to obtain specific methane yields:

$$Y_{\text{case}} = \frac{V_{\text{CH}_4,\text{final}}}{\text{VS}_{\text{added}}}$$

where $V_{\text{CH}_4,\text{final}}$ is the last measured cumulative methane volume for a given experimental condition. This allows direct comparison between different biochar doses and with theoretical predictions.

2.2. Biochar Enhancement Factor (α)

The enhancement factor quantifies the fractional increase in methane yield per unit dose of biochar. It is defined as:

$$\alpha = \frac{\left(\frac{Y_{\text{with}}}{Y_{\text{without}}} - 1\right)}{B}$$

where:

- Y_{with} = methane yield at the optimum biochar dose (mL/g VS)
- Y_{without} = methane yield without biochar (control)
- B = biochar dose (mass fraction, e.g., 0.05 for 5% w/w)

This linearised formulation assumes that the relative yield increase scales linearly with biochar dose over the tested range – a simplification that is verified by the experimental data. α is a **dimensionless empirical constant** that encapsulates all non-reactive enhancement mechanisms (e.g., improved interspecies electron transfer, buffering capacity, microbial immobilisation).

2.3. Effective Kinetic Constant for RCSTR

In Aspen Plus, the acetoclastic methanogenesis step ($CH_3COOH \rightarrow CH_4 + CO_2$) is modelled using power-law kinetics in a continuous stirred-tank reactor (RCSTR). The base reaction rate without biochar is:

$$r = k_{\text{base}} \cdot C_{\text{acetate}}^{n}$$

with n typically 1 (first-order). The biochar effect is incorporated by multiplying the base rate constant by a factor $(1+\alpha B)$:

$$k_{\text{eff}} = k_{\text{base}}(1+\alpha B)$$

Thus,

$$r_{\text{with biochar}} = k_{\text{eff}} \cdot C_{\text{acetate}}^{n} = k_{\text{base}}(1+\alpha B)C_{\text{acetate}}^{n}$$

This formulation preserves the **stoichiometric inertness** of biochar – it does not appear in any reaction equation, only in the kinetic constant.

2.4. Buswell Equation for Theoretical Methane Potential

Given the empirical formula of the organic fraction ($C_nH_aO_bN_c$), the maximum methane production (assuming complete conversion to CH_4 and CO_2, with NH_3 as nitrogen product) is:

$$C_nH_aO_bN_c + \left(n - \frac{a}{4} - \frac{b}{2} + \frac{3c}{4}\right) H_2O \rightarrow \left(\frac{n}{2} + \frac{a}{8} - \frac{b}{4} - \frac{3c}{8}\right) CH_4 + \left(\frac{n}{2} - \frac{a}{8} + \frac{b}{4} + \frac{3c}{8}\right) CO_2 + c\, NH_3$$

The moles of CH_4 per mole of carbon are:

$$\nu_{CH_4} = \frac{1}{2} + \frac{a}{8} - \frac{b}{4} - \frac{3c}{8}$$

To convert to mL CH_4 per gram of volatile solids, we first compute the molar mass of the empirical formula per carbon atom:

$$M_{\text{C-unit}} = 12.01 + a \cdot 1.008 + b \cdot 16.00 + c \cdot 14.01$$

Then:

$$Y_{\text{theor}} = \frac{\nu_{CH_4}}{M_{\text{C-unit}}} \times 22400 \left[\frac{\text{mL } CH_4}{\text{g VS}}\right]$$

where 22400 mL is the molar volume of an ideal gas at 0°C and 1 atm (STP). This theoretical value serves as an upper bound and validation target.

2.5. Derivation of RYIELD Fractions from Ultimate Analysis

The RYIELD block in Aspen Plus decomposes the non-conventional component FOODWASTE into conventional intermediates (acetate, H_2, CO_2, H_2O) and an inert residue DIGEST. The fractions must sum to 1.0 on a mass basis. The script determines the Digest fraction from the ash content of the food waste:

$$f_{\text{digest}} = \max\left(0.10,\ \min\left(0.30,\ \frac{\text{Ash}_{\text{VS}}}{1 - \text{Ash}_{\text{VS}}} + 0.05\right)\right)$$

where Ash_{VS} is the ash weight fraction on a volatile solids basis. The remaining fractions (acetate, H_2, CO_2, H_2O) are taken from literature values (Angelidaki et al., 2018) and then re-normalised so that all five sum to 1.0. This ensures mass closure while anchoring the decomposition to the feedstock's mineral content.

3. Algorithm (Step-by-Step)

The algorithm follows a deterministic, sequential workflow. Pseudo-code is provided below, followed by a flow diagram description.

3.1. Input Phase

text

```
1. Load AD_Project_Input.xlsx using pandas.
   - Sheet: 'Daily_Methane' → DataFrame `methane`
   - Sheet: 'Process_Inputs' → DataFrame `process`
   - Sheet: 'Ultimate_Analysis' → DataFrame `ultimate`

2. Define helper function `get_process_param(name)`:
   - Extract row where 'Parameter' == name
   - Return float of 'Value'; raise KeyError if missing.
```

3.2. Data Normalisation and Optimum Dose Detection

text

```
3. VS_added = get_process_param('VS_added')
4. final_row = last row of `methane` (index -1)
5. For each column in `methane` (excluding 'Day'):
   - normalised_value = final_row[col] / VS_added
   - Store in dictionary `normalized[col]`

6. Identify control column: 'CH4_No_Biochar' if exists, else 'No_Biochar'
7. Identify biochar columns: all keys in `normalized` except control, with non-None values
8. Find opt_col = key with maximum normalised value among biochar columns
9. Extract dose from opt_col using regular expression r'(\d+(?:\.\d+)?)pct'
   - Convert to fraction (e.g., '5pct' → 0.05)
   - If regex fails, fallback to get_process_param('Optimum_Biochar_Dose')
```

3.3. Methane Yield Table

text

```
10. Create list of [case_name, yield] for each `normalized` entry
    - case_name = column name stripped of 'CH4_' and '_Biochar'
11. Form DataFrame `yield_table` with columns 'Case', 'Methane_Yield_mL_CH4_gVS'
```

3.4. Alpha Factor Calculation

text

```
12. y_without = normalized[control_col]
13. y_with = normalized[opt_col]
14. B = opt_dose
15. alpha = ((y_with / y_without) - 1) / B
16. alpha_table = DataFrame with rows: Y_without, Y_with, Biochar_Dose, Alpha
```

3.5. Effective Kinetic Constant

text

```
17. base_k = get_process_param('Base_k')
18. k_eff = base_k * (1 + alpha * B)
19. k_table = DataFrame with rows: Base_k, Effective_k
```

3.6. RYIELD Fractions from Ultimate Analysis

text

```
20. Define function `calculate_ryield_fractions(ultimate_df)`:
    a. Locate row where 'Material' == 'foodwaste' (case-insensitive)
    b. Extract C_wt%, H_wt%, O_wt%, N_wt%, Ash_wt%
    c. Compute ash_vs = Ash_wt% / (1 - Ash_wt%)  (approximate VS basis)
    d. Set frac_digest = clamp(ash_vs + 0.05, 0.10, 0.30)
    e. Set literature base fractions:
       frac_acetate_base = 0.44, frac_H2_base = 0.07, frac_CO2_base = 0.19, frac_H2O_base = 0.15
    f. Sum_total = base_sum + frac_digest
    g. Normalise each fraction: frac_i = base_i / sum_total
    h. Return DataFrame with products and fractions.
```

i. Also compute theoretical Buswell methane using C,H,O,N and return that value.

21. ryield, theoretical_buswell = calculate_ryield_fractions(ultimate)

3.7. Buswell Validation Table

text

22. experimental_opt = y_with (from step 13)
23. buswell_table = DataFrame with:
    - Theoretical_CH4_mL_gVS (Buswell) = theoretical_buswell
    - Experimental_optimum_CH4_mL_gVS = experimental_opt
    - Difference_% = 100 * (exp_opt / theor - 1)
    - Note = explanatory text

3.8. Output Phase

text

24. Create ExcelWriter for AD_Project_Output.xlsx (engine='openpyxl')
25. Write DataFrames to sheets:
    - yield_table → 'Methane_Yield'
    - alpha_table → 'Alpha_Calc'
    - k_table → 'Kinetic_k'
    - ryield → 'RYIELD_Table'
    - buswell_table → 'Buswell_Validation'
26. Print completion message.

3.9. Error Handling

- All pd.read_excel calls are wrapped in try-except to catch missing files/sheets.
- get_process_param raises explicit KeyError if a parameter is absent.
- Column name matching for biochar dose uses regex, with fallback to manual input.
- If no biochar columns are found, the script aborts with a descriptive error.

4. Flow Diagram (Textual Representation)

text

```
[Start]
  │
  ▼
Read AD_Project_Input.xlsx
  │
  ├──► Daily_Methane ──► [A]
  ├──► Process_Inputs ─► [B]

  |
  ▼
Assemble output DataFrames:
  Methane_Yield | Alpha_Calc | Kinetic_k | RYIELD_Table | Buswell_Validation
  |
  ▼
Write to AD_Project_Output.xlsx
  |
  ▼
[End]
```

5. Scientific and Practical Justification

5.1. Why Auto-Detection of Optimum Dose is Essential

Manual selection of the “best” biochar dose (e.g., always using 5%) introduces bias. The automated peak detection ensures that the enhancement factor α is calculated from the truly optimal experimental condition, which may vary with feedstock composition or biochar type. This makes the analysis objective and reproducible.

5.2. Role of the Buswell Validation Sheet

The comparison between theoretical (Buswell) and experimental methane yields serves two purposes:

- **Model credibility**: If experimental yields exceed the theoretical maximum, it indicates either measurement error or an unrealistic model assumption. In practice, biochar can increase yields beyond the Buswell prediction because the latter assumes no kinetic limitations – a positive difference is acceptable and can be discussed as “kinetic unlocking”.
- **Quality control**: Large deviations (>20%) trigger a re-examination of the ultimate analysis or the BMP protocol.

5.3. Handling of Digest (Residue) in RYIELD

The digest fraction is not arbitrary; it is tied to the ash content of the feedstock. This is mechanistically correct because ash is non-biodegradable and will remain as solid residue. The clamp bounds (10–30%) reflect typical food waste digestate ranges from literature, preventing extreme values when ash measurements are noisy.

5.4. Connection to Aspen Plus

The four numerical outputs have a direct one-to-one mapping to Aspen Plus inputs:

- Methane_Yield → Validates the overall simulation result.
- Alpha_Calc → Justifies the kinetic enhancement factor used in the RCSTR.
- Kinetic_k → Entered as the pre-exponential factor in the Power Law kinetics form.
- RYIELD_Table → Defines the yield distribution in the RYIELD block for hydrolysis/acidogenesis.
- Buswell_Validation → Provides a theoretical baseline for discussion in the thesis.

6. Assumptions and Limitations (To Be Discussed in Thesis)

1. **Linearity of α with dose** – Assumes that the fractional methane increase per unit biochar is constant across doses. Non-linear effects (e.g., saturation) are ignored but can be detected by inspecting the raw yield table.
2. **First-order kinetics** – The RCSTR is modelled with a first-order dependence on acetate concentration ($n = 1$). This is a simplification; if experimental data suggest a different order, the user must modify the code accordingly.
3. **STP conditions** – The Buswell equation uses 22.4 L/mol at 0°C and 1 atm. Actual digester conditions (e.g., 35°C) would give slightly higher volumes; the script uses STP for consistency with BMP standard reporting.
4. **Neglect of microbial growth** – The kinetic model does not include biomass explicitly; it is lumped into the rate constant. This is acceptable for steady-state simulation but limits dynamic predictions.
5. **Literature-derived acidogenesis fractions** – While the digest fraction is adjusted by ash content, the relative yields of acetate, H_2, CO_2, and H_2O are fixed to typical values. For a truly data-driven model, these would be replaced by experimental VFA profiles.

7. Conclusion

The Python script operationalises a robust, data-driven methodology to translate batch BMP experiments into kinetic and stoichiometric parameters suitable for Aspen Plus simulation. Its core scientific contribution is the quantification of the biochar enhancement factor α, which captures the catalytic effect of biochar without violating mass conservation. By automatically determining the optimum dose and deriving RYIELD fractions from elemental analysis, the code ensures that the Aspen model is both specific to the experimental feedstock and reproducible across different studies. The inclusion of a Buswell validation sheet provides an immediate check of thermodynamic consistency and strengthens the thesis argument. This algorithm forms a complete digital pipeline from laboratory to process simulation, fully documented and ready for integration into a PhD dissertation.

Reference for acidogenesis fractions (example):

Angelidaki, I., et al. (2018). “Biogas from anaerobic digestion: processes and applications.” In *Bioenergy Research: Advances and Applications*, Elsevier, 329-348.

Aspen Plus Simulation

Python provides:

- optimum biochar dose
- methane yield data
- biochar enhancement factor α
- effective kinetic constant k_{eff}
- RYIELD decomposition fractions

Aspen uses these values to simulate:
complete anaerobic digestion process
and validate the methane production.
This creates the final connection:
Lab Work → Python → Aspen Plus → Final Validation

Why We Use Aspen Plus
Lab experiment gives:
real methane production
but it cannot easily show:

- internal reaction pathways
- gas-liquid distribution
- reactor behavior
- effect of kinetics on methane formation
- optimization of operating conditions

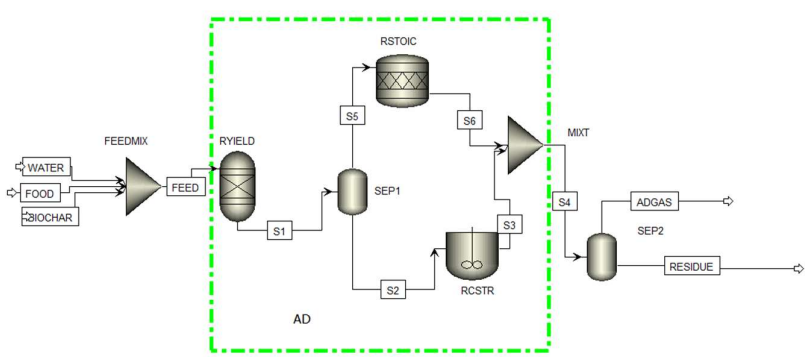
Aspen helps to simulate all these scientifically.
It makes the thesis strong and publishable.

Important Scientific Assumption
Biochar does NOT react
Biochar is treated as:
non-conventional (NC) unreacted additive
Its role is only:
kinetic enhancement
This means:

- no reaction in RYIELD
- no reaction in RSTOIC
- no reaction in RCSTR stoichiometry

Only:
RCSTR kinetic constant changes
This is the most important part of your model.

Final Aspen Flowsheet



This is the final correct model.

Step 1 — Component Definition

Conventional Components
These are normal components:

- H_2O
- CH_4
- CO_2
- H_2
- Acetic Acid (or ACETIC)
- NH_3 (optional)

These are used in reactors.

Non-Conventional Components
These are:

- FOODWASTE
- BIOCHAR
- DIGEST

These are defined using:

- proximate analysis
- ultimate analysis

from your lab data.

Why
Because food waste and biochar are not pure chemicals.
They are solid complex materials.
So Aspen uses:
NC components
for realistic simulation.

Step 2 — Property Method
Use:
NRTL
or
ELECNRTL (optional)
Recommended:
NRTL
for thesis simplicity.

Why
Because AD contains:

- water
- organic acids
- gases
- non-ideal liquid behavior

NRTL handles this well.

Step 3 — FEEDMIX Block

Purpose
Mix:

- food waste
- water
- biochar

to create:

FEED stream

Why
This represents the digester feed.
Water provides slurry condition.
Biochar enters here and stays unreacted.

Step 4 — RYIELD Block

Purpose
Represents:
Hydrolysis + Acidogenesis
Food waste is decomposed into intermediates.
Reaction:
FOODWASTE
→ Acetate + H_2 + CO_2 + H_2O + Digest
Important:
NO methane here

Why
Real AD happens in stages:

1. Hydrolysis
2. Acidogenesis
3. Acetogenesis
4. Methanogenesis

Methane should form later.
This makes model scientifically correct.

RYIELD Input Fractions
Example:

Product	Fraction
Acetate	0.44
H_2	0.07
CO_2	0.19
H_2O	0.15
Digest	0.15

These come from:

- Buswell equation
- COD balance
- BMP data
- literature validation

Step 5 — SEP1 Block

Purpose
Separate RYIELD output into:
Gas Stream → S5
Contains:

- H_2
- CO_2

Liquid Stream → S2
Contains:

- Acetate
- Water
- Digest

- Biochar

Why
Because methane forms by:
two different pathways
So both must be treated separately.
Very important.

Step 6 — RSTOIC Block

Purpose
Represents:
Hydrogenotrophic Methanogenesis
Reaction:

$$CO_2 + 4H_2 \rightarrow CH_4 + 2H_2O$$

Why
Gas-phase H2 and CO2 must be converted to methane.
This is one major methane pathway.
Simple and strong.

Setup
Use:
Fractional conversion
Example:
70–90%
depending on experimental support.

Step 7 — RCSTR Block

Purpose
Represents:
Acetoclastic Methanogenesis
Reaction:

$$CH_3COOH \rightarrow CH_4 + CO_2$$

This is the main methane production step.
Most methane comes from here.

Why
Acetate is the major methane precursor in AD.
This is where:
biochar effect is modeled
Most important block.

RCSTR Kinetic Equation
Conceptually:

$$r = k(1 + \alpha B)C$$

where:

- k= base kinetic constant
- α= biochar enhancement factor
- B= biochar dose
- C= acetate concentration

Aspen uses simplified form:

$$r = k_{eff}C$$

where:

$$k_{eff} = k(1 + \alpha B)$$

Example
From Python:
Base k = 0.25
Alpha = 6.8
B = 0.05
Then:
k_eff = 0.335
This is entered in:
Power Law kinetics
inside RCSTR.

Your Current Setup
From your screenshot:
k = 0.35
n = 0
E = 0
Recommended improvement:
k = 0.35
n = 1
E = 0
because:

$$r = kC^n$$

and first-order reaction is more realistic.

Step 8 — MIXT Block

Purpose
Mix methane from:

- RSTOIC
- RCSTR

to create:
total biogas stream

Why
Final methane comes from both pathways.
So both must be combined.

Step 9 — SEP2 Block

Purpose
Separate final stream into:
ADGAS
Final methane-rich biogas
RESIDUE
Digestate + water + biochar

Why
To obtain final usable product stream.
This matches real digester output.

Final Outputs

ADGAS
Contains:

- CH_4
- CO_2
- trace gases

Used for:
methane yield validation

RESIDUE
Contains:

- digest
- water
- unreacted biochar

This proves:
biochar remains unreacted
Very strong thesis point.

Model Validation
Compare:
Aspen methane yield
with
experimental methane yield
Example:

Source	Methane Yield
Lab BMP	429
Aspen	417

Good agreement means:
model is valid

Final Scientific Conclusion
Biochar does not participate in chemical reactions.
It improves methane production only by increasing:
methanogenesis reaction kinetics
inside RCSTR.
This is the strongest scientific contribution of your work.
